Digital Printing Control: Print Shop in a Box

The digital print process is remarkably challenging because it involves many process and digital actuators for applying a range of advanced control techniques. Many of the new challenges listed here opened the door for the insertion of new control theory. Numerous Xerox® printing systems (for example, iGen3®, iGen4®, DocuColor® 7002, DocuColor® 8002, DocuColor® 5000, DocuColor® 8000, iGen4® 220 Perfecting Press, Xerox® Color 800/1000 Presses, ColorQube™) produce high-quality prints using these control innovations to generate several billion dollars in revenue.

Control Challenges for Digital Printing

- Optimize job workflows via feedback from the press (streamline workflow and free operators to focus on running the print jobs)
- Increase productivity with automated color management tools
- Provide consistent color image quality (first page, between pages, job to job, operator to operator, machine to machine)
- Provide offset look and feel with best image quality, no nonuniformity, and no defects
- Provide automated calibration (completely hands-free), spot color (Pantone® matching), more stable color
- Allow mix-and-match of press configurations (any application to any printer, any finisher and feeder on any marking engine)
- Manage time-sensitive activities of various machine modules
- Adjust color dynamically using internal process control feedback loops
- Provide active control of registration of all color separations
- Compensate for sheet-to-sheet differences in the paper as well as drive system wear, temperature variations, and the like

A learning algorithm is incorporated for paper registration control. Singular value decomposition is used for dimensionality reduction, to reduce gray-level samples while constructing spatial toner reproduction curves or functions on photoconductors. Ideas from cooperative control theory and simultaneous perturbation stochastic approximation have been used for gray-component replacement in the color management profiling (ICC profile) system. K-means clustering for spectral reconstruction in real time allowed the use of a low-cost LED-based spectrophotometer. For complex printing jobs, scheduling of paper sheets is a difficult operation; constraint-based scheduling algorithms are used to solve it. Motion and unevenness in motion can induce disturbances in the printing process. Repetitive control and adaptive feedforward control algorithms help mitigate the effects of these disturbances. The printers integrate diagnostic and self-monitoring features using statistical process control, among other methods.

Inventions and Innovations

Xerox’s new printing systems are tours de force for control technology! Highlights include:

- A hierarchical automation architecture that distinguishes between different color control horizon levels.
- The control design includes classical single-input single-output (SISO) PID-type controllers, with delay and anti-windup compensation, for several subsystems.
- Toner concentration control, although a SISO system, is especially challenging. The solution integrates a Kalman filter to handle noisy and unreliable measurements, a Smith predictor to handle the delay, and an anti-windup compensator for constraint management.
- Several multivariable controllers are also part of the design. These include state feedback, pole placement, model predictive control, and linear quadratic regulator designs. Systems under multivariable control include electrostatic control, spot color calibration, and color management profiling (ICC profile).
